

# Abstract Query Languages:

## Relational Algebra and Relational Calculus

Dr. Sambit Bakshi

NIT Rourkela

February 26, 2024

# Outline

- 1 Introduction to Query Languages
- 2 Introduction to Query Languages
- 3 Relational Algebra
- 4 Relational Calculus
- 5 Tuple Relational Calculus
- 6 Domain Relational Calculus

# Introduction to Query Languages

- The schema of a relation defines its structure
- The relationships define constraints on the attributes / tuples

What would we do with the schema and constraints if there is no way to manage data in a relation!

**Query languages help in manipulate data in a relation**

# Introduction to Query Languages

Database Model	Query Model
Relational Model set-based (no duplicate tuples)	Relational Algebra (Procedural) and Relational Calculus (Non-procedural / Declarative)

These Query models are **abstract** or **theoretical**.

Relational Algebra and Relational Calculus (with only safe queries) are equivalent.

In practice, Relational model is implemented as RDBMS, and the query model is implemented as SQL.

A language is called **relationally complete** if it has capacity to express every query expressible through relational algebra. SQL is **relationally complete**.

# Introduction to Query Languages

## Cardinality and Degree / Arity of a Relation

- **Degree / Arity of a relation** is the number of attributes / columns of the relation.  
It is an intrinsic property of a relation.
- **Cardinality of a relation** is the number of tuples / rows of the relation.  
It is not an intrinsic property of a relation, and represents a state of the relation.

# Basic Operations

There are **SIX** basic operations:

## Unary operations:

- **Selection** ( $\sigma$ ): Selects a subset of tuples / rows from a relation
- **Projection** ( $\pi$ ): Retains a subset of columns from a relation
- **Rename** ( $\rho$ ): Renames a relation

## Binary operations:

- **Cross Product / Cartesian Product** ( $\times$ ): Allows to combine two relations
- **Difference / Set difference** ( $-$ ): Returns tuples present in one relation but not in the other
- **Union** ( $\cup$ ): Consolidates tuples in two relations

# More Operations

- **Intersection** ( $\cap$ ): Returns tuples present in both relations
- **Join** ( $\bowtie$ ): Allows to combine two or more relations  
There are several types of joins: semi join ( $\ltimes, \ltimes$ ), left outer join ( $\ltimes\sqcup$ ), right outer join ( $\sqcup\ltimes$ ), full outer join ( $\ltimes\sqcup\ltimes$ )
- **Division** ( $/$ ): Returns those tuples of a relation which subsets tuples of another table
- **Assignment** ( $\leftarrow$ ): Assigning the output to a relation

# Selection operation

**Selection ( $\sigma$ ):** selects a subset of tuples / rows from a relation.

Also called as **horizontal partitioning**.

Syntax:  $\sigma_{\langle \text{CONDITION} \rangle}(\langle \text{RELATION} \rangle)$

EMP(EID, ENAME, ESAL, DEPT)

<u>EID</u>	ENAME	ESAL	DEPT
001	ABC	10500	2
002	ABD	9000	4
003	DEF	11000	4
004	DBC	12000	4

Select details of employees with salary (ESAL) greater than INR 10000 from the table EMP(EID, ENAME, ESAL, DEPT) given beside

$\sigma_{\text{ESAL} > 10000}(\text{EMP})$

EID	ENAME	ESAL	DEPT
001	ABC	10500	2
003	DEF	11000	4
004	DBC	12000	4

Select details of employees working in department (DEPT) '4' from the table EMP mentioned beside

$\sigma_{\text{DEPT} = 4}(\text{EMP})$

EID	ENAME	ESAL	DEPT
002	ABD	9000	4
003	DEF	11000	4
004	DBC	12000	4

# Selection operation

**Selection ( $\sigma$ ):** selects a subset of tuples / rows from a relation.

Also called as **horizontal partitioning**.

Syntax:  $\sigma_{\langle \text{CONDITION} \rangle}(\langle \text{RELATION} \rangle)$

EMP(EID, ENAME, ESAL, DEPT)

EID	ENAME	ESAL	DEPT
001	ABC	10500	2
002	ABD	9000	4
003	DEF	11000	4
004	DBC	12000	4

Select details of employees of department (DEPT) '4' having salary (ESAL) greater than INR 10000 from the table EMP mentioned beside

$\sigma_{\text{DEPT} = 4 \text{ AND } \text{ESAL} > 10000}(\text{EMP})$  (cascading conditions)

$\sigma_{\text{DEPT} = 4}(\sigma_{\text{ESAL} > 10000}(\text{EMP}))$  (nested conditions)

$\sigma_{\text{ESAL} > 10000}(\sigma_{\text{DEPT} = 4}(\text{EMP}))$  (nested conditions)

EID	ENAME	ESAL	DEPT
003	DEF	11000	4
004	DBC	12000	4

As order of nesting of conditions does not affect the output of Select ( $\sigma$ ) operator, it is **commutative**

# Selection operation

- Selection operator works on **a single tuple at a time**
- The **CONDITION** involved in selection operation **MUST** be a boolean expression (or a logical combination of more than one boolean expressions)
- Selection operator may reduce the cardinality of a relation when it acts on, i.e.,  
 $|\sigma_{\langle \text{CONDITION} \rangle}(\langle \text{RELATION} \rangle)| \leq |\langle \text{RELATION} \rangle|$
- Selection operator does not alter the arity of a relation
- Selection operator can act on a relation or any relational algebra expression resulting on a table
- Selection operator is commutative

# Projection operation

**Projection ( $\pi$ ):** selects a subset of attributes from a relation.

Also called as **vertical partitioning**.

Syntax:  $\pi_{\langle \text{ATTRIBUTES} \rangle}(\langle \text{RELATION} \rangle)$

EMP(EID, ENAME, ESAL, DEPT)

<u>EID</u>	ENAME	ESAL	DEPT
001	ABC	10500	2
002	ABD	9000	4
003	DEF	11000	4
004	DBC	12000	4

Extract Employee IDs EID and Names ENAME of employees from the table EMP(EID, ENAME, ESAL, DEPT) given beside

$\pi_{\text{EID}, \text{ENAME}}(\text{EMP})$

EID	ENAME
001	ABC
002	ABD
003	DEF
004	DBC

Extract departments DEPT of employees from the table EMP mentioned above.

$\pi_{\text{DEPT}}(\text{EMP})$

DEPT
2
4

Removes duplicates!

# Projection operation

## Is Projection ( $\pi$ ) operation commutative?

We know, for a projection operation to work, the attributes it retrieves must be a subset of the attributes of the input relation.

For  $\pi_{\langle \text{ATTRIBUTES}_2 \rangle}(\pi_{\langle \text{ATTRIBUTES}_1 \rangle}(\langle \text{RELATION} \rangle))$  to be valid, the following condition must be true:  
 $\langle \text{ATTRIBUTES}_2 \rangle \subseteq \langle \text{ATTRIBUTES}_1 \rangle$

Also, for projection to be commutative,

$$\pi_{\langle \text{ATTRIBUTES}_2 \rangle}(\pi_{\langle \text{ATTRIBUTES}_1 \rangle}(\langle \text{RELATION} \rangle)) = \pi_{\langle \text{ATTRIBUTES}_1 \rangle}(\pi_{\langle \text{ATTRIBUTES}_2 \rangle}(\langle \text{RELATION} \rangle))$$

However,  $\pi_{\langle \text{ATTRIBUTES}_2 \rangle}(\pi_{\langle \text{ATTRIBUTES}_1 \rangle}(\langle \text{RELATION} \rangle)) \neq \pi_{\langle \text{ATTRIBUTES}_2 \rangle}(\langle \text{RELATION} \rangle)$

Hence projection is not commutative.

# Projection operation

- Projection operator can act on a relation or any relational algebra expression resulting on a table
- The  $\langle \text{ATTRIBUTES} \rangle$  involved in projection operation MUST be a subset (may be equal) of all attributes in  $\langle \text{RELATION} \rangle$
- Projection operator may reduce the arity / degree of a relation when it acts on, i.e.,  $\text{Arity of } \pi_{\langle \text{ATTRIBUTES} \rangle}(\langle \text{RELATION} \rangle) \leq \text{Arity of } \langle \text{RELATION} \rangle$
- Projection operator may alter the cardinality of a relation as it removes duplicate tuples from output

i.e.,  $|\pi_{\langle \text{ATTRIBUTES} \rangle}(\langle \text{RELATION} \rangle)| \leq |\langle \text{RELATION} \rangle|$

If  $\langle \text{ATTRIBUTES} \rangle$  is a superkey, then

$|\pi_{\langle \text{ATTRIBUTES} \rangle}(\langle \text{RELATION} \rangle)| = |\langle \text{RELATION} \rangle|$

Projection operation defined in abstract relational algebra language eliminates duplicates, but projection operator in SQL retains duplicates!

Projection operation is not commutative.

# Cascading Selection and Projection operation

EMP(EID, ENAME, ESAL, DEPT)

<u>EID</u>	ENAME	ESAL	DEPT
001	ABC	10500	2
002	ABD	9000	4
003	DEF	11000	4
004	DBC	12000	4

Extract Employee IDs EID and Names ENAME of employees whose salary ESAL is greater than INR 10000 from the table EMP(EID, ENAME, ESAL, DEPT) given beside

TEMP  $\leftarrow \sigma_{\text{ESAL} > 10000}(\text{EMP})$   
 ANS  $\leftarrow \pi_{\text{EID}, \text{ENAME}}(\text{TEMP})$

OR IT CAN ALSO BE WRITTEN INLINE AS:

$\pi_{\text{EID}, \text{ENAME}}(\sigma_{\text{ESAL} > 10000}(\text{EMP}))$

EID	ENAME
001	ABC
003	DEF
004	DBC

- Please note that  $\pi_{\text{EID}, \text{ENAME}}(\sigma_{\text{ESAL} > 10000}(\text{EMP})) \neq \sigma_{\text{ESAL} > 10000}(\pi_{\text{EID}, \text{ENAME}}(\text{EMP}))$ , i.e., the roles of selection and projection cannot be commutative. Always selection acts first, and then projection.

# Rename operation

- Syntax: Renaming relation name and attributes:  
 $\rho_{\langle \text{OUTPUT\_RELATION} \rangle}(\langle \text{OUTPUT\_ATTRIBUTES} \rangle)(\langle \text{INPUT\_RELATION} \rangle)$
- Syntax: Renaming relation name only (and not attributes):  
 $\rho_{\langle \text{OUTPUT\_RELATION} \rangle}(\langle \text{INPUT\_RELATION} \rangle)$
- Syntax: Renaming attributes only (and not relation name):  
 $\rho_{\langle \text{OUTPUT\_ATTRIBUTES} \rangle}(\langle \text{INPUT\_RELATION} \rangle)$
- The input for rename operator can be a relation or a relational algebra expression
- Rename operation is a special type of projection

# Set operations

The set operations Union ( $\cup$ ), Intersection ( $\cap$ ), Difference ( $-$ ) are binary Operations.

**Union** ( $\cup$ ): Consolidates tuples in two relations

**Intersection** ( $\cap$ ): Extracts only common tuples from two relations

**Difference** ( $-$ ): Extracts tuples present exclusively in first relation (but not present in second relation)

# Set operations

**Union Compatibility:** The two input relations should have (i) same degree and (ii) same domain for every attribute

**Union Compatibility** is decided based on intrinsic properties of two relations, not based on it's state.

$R \cup S$  automatically stores the result in first operand, i.e.,  $R$ .

Union eliminates duplicates from the output and returns the common tuples only once in output, and intersection cannot have duplicates.

Intersection is a derived operation, i.e.

$$R \cap S = R - (R - S) = S - (S - R)$$

# Set operations

Union and intersection operations are commutative, i.e.

$$R \cup S = S \cup R \text{ and } R \cap S = S \cap R$$

Union and intersection operations are associative, i.e.

$$(R \cup S) \cup T = R \cup (S \cup T) \text{ and } (R \cap S) \cap T = R \cap (S \cap T)$$

Difference / minus is not commutative, i.e.,

$$R - S \neq S - R$$

# Cardinality analysis of set operations

**Inputs:** A having cardinality  $m$ , B having cardinality  $n$

Operation ↓	Venn Diagram Representation ↓	Minimum Cardinality	Maximum Cardinality
$A \cup B$		$\max(m, n)$	$m+n$
$A \cap B$		0	$\min(m, n)$
$A - B$		0	$m$

# Cross Product / Cartesian Product

Cross product / Cartesian product ( $\times$ ) is a binary Operation.

The input relations need not be union compatible for participating in cross product.

**Arity of  $R \times S$**  = (Arity of  $R$  + Arity of  $S$ )

**Cardinality of  $R \times S$**  = (Cardinality of  $R \times$  Cardinality of  $S$ )

# Cross Product / Cartesian Product

$R(A, B, C)$

A	B	C
a <sub>1</sub>	b <sub>1</sub>	c <sub>1</sub>
a <sub>2</sub>	b <sub>2</sub>	c <sub>2</sub>
a <sub>3</sub>	b <sub>3</sub>	c <sub>3</sub>

$S(D, E)$

D	E
d <sub>1</sub>	e <sub>1</sub>
d <sub>2</sub>	e <sub>2</sub>

$P(A, B, C, D, E) \leftarrow R(A, B, C) \times S(D, E)$

A	B	C	D	E
a <sub>1</sub>	b <sub>1</sub>	c <sub>1</sub>	d <sub>1</sub>	e <sub>1</sub>
a <sub>1</sub>	b <sub>1</sub>	c <sub>1</sub>	d <sub>2</sub>	e <sub>2</sub>
a <sub>2</sub>	b <sub>2</sub>	c <sub>2</sub>	d <sub>1</sub>	e <sub>1</sub>
a <sub>2</sub>	b <sub>2</sub>	c <sub>2</sub>	d <sub>2</sub>	e <sub>2</sub>
a <sub>3</sub>	b <sub>3</sub>	c <sub>3</sub>	d <sub>1</sub>	e <sub>1</sub>
a <sub>3</sub>	b <sub>3</sub>	c <sub>3</sub>	d <sub>2</sub>	e <sub>2</sub>

- Cross product is commutative, i.e,  $R \times S = S \times R$
- Cross product is associative, i.e.,  $(R \times S) \times T = R \times (S \times T)$
- In most practical cases, such unconditional linking of every tuple of a relation with every tuple of another relation is meaningless.

## Join

Syntax:  $P \leftarrow R \bowtie_{\langle \text{join\_condition} \rangle} S$

$R(A, B, C)$

A	B	C
a <sub>1</sub>	b <sub>1</sub>	c <sub>1</sub>
a <sub>2</sub>	b <sub>2</sub>	c <sub>2</sub>
a <sub>3</sub>	b <sub>3</sub>	c <sub>3</sub>

$P(A, B, C, D, E) \leftarrow R(A, B, C) \bowtie_{A=D} S(D, E)$

A	B	C	D	E
a <sub>1</sub>	b <sub>1</sub>	c <sub>1</sub>	a <sub>1</sub>	b <sub>1</sub>
a <sub>2</sub>	b <sub>2</sub>	c <sub>2</sub>	a <sub>2</sub>	b <sub>2</sub>

$S(D, E)$

D	E
a <sub>1</sub>	b <sub>1</sub>
a <sub>2</sub>	b <sub>2</sub>

- Join product is commutative, i.e,  $R \bowtie_{\langle \text{join\_condition} \rangle} S = S \bowtie_{\langle \text{join\_condition} \rangle} R$
- Arity of  $R \bowtie S = (\text{Arity of } R + \text{Arity of } S)$
- Minimum Cardinality of  $R \bowtie S = 0$
- Maximum Cardinality of  $R \bowtie S = (\text{Cardinality of } R \times \text{Cardinality of } S)$

# Join

$\langle \text{join\_condition} \rangle$  is always a boolean condition.

$\langle \text{join\_condition} \rangle$  is generally not a condition where check on a attributes on a single participating relation is checked. Such conditions can always be applied before join. Why would we apply such conditions while join!

$\langle \text{join\_condition} \rangle$  is usually a condition where check between attributes of both participating relations is performed.

$\langle \text{join\_condition} \rangle$  is hence denoted as  $R_i \theta S_j$  where  $R_i$  and  $S_j$  are two attributes from the relations respectively, and  $\theta$  is the binary boolean operation between them.  $\theta$  can be checking if they are equal, or unequal, or one is greater than other etc.

As the operation between attributes from different relations is classically represented by  $\theta$ , it is also called **theta join**.

# Join

$\langle \text{join\_condition} \rangle$  is very common in some practical cases, as we may check relation between two related attributes.

For this, a special type of join operation, called **natural join** ( $*$ ) is used where  $\langle \text{join\_condition} \rangle$  is not explicitly written. An equality check between the attribute pairs having same name is done, and accordingly the result of natural join is computed.

$R(A, B, C)$

A	B	C
$a_1$	$b_1$	$c_1$
$a_2$	$b_2$	$c_2$
$a_3$	$b_3$	$c_3$

$P(A, B, C) \leftarrow R(A, B, C) * S(A)$

A	B	C

Is division associative? Draw a Venn Diagram of set of three relations and check if  $R/(S/T)$  and  $(R/S)/T$  contains same set of attributes.

# Division

Division is not a basic operation, that means, division operation should be expressed in terms of basic operations.

To express division ( $T \leftarrow R / S$ ) with basic operations:

**Step# 1:**  $T1 \leftarrow \pi_{(R-S)} (R)$

**Step# 2:**  $T2 \leftarrow \pi_{(R-S)} ((S \times T1) - R)$

**Step# 3:**  $T \leftarrow T1 - T2$

# Outer Join

All join functions learn before are **inner join**, in which the dangling tuples (those tuples of one relation not having a referred value in other relation) does not appear in output.

Sometimes we may need those tuples which does not have a match in other relation.

A join providing such tuples in output is called **outer join**.

**left outer join** (  $R \bowtie\!\!\!\lrcorner S$  ) retains the dangling tuples of  $R$  but not those of  $S$

**right outer join** (  $R \bowtie\!\!\!\rceil S$  ) retains the dangling tuples of  $S$  but not those of  $R$

**full outer join** (  $R \bowtie\!\!\!\lrcorner\!\!\!\rceil S$  ) retains the dangling tuples of both  $R$  and  $S$

A meme I found on internet!

# Semi-join

A **semi-join** between two relations returns tuples from the one relation where one or more matches (according to join condition) are found in tuples of the other relation.

Though a tuple in one relation may have match with more than one tuples of the other relation, the tuple will appear only once in output.

**left semi-join** ( $R \ltimes S$ ) retains those tuples of  $R$  which have a match with  $S$

**right semi-join** ( $R \rtimes S$ ) retains those tuples of  $S$  which have a match with  $R$

**semi-join** is not commutative.

# Anti-join

A **anti-join** or **anti semi-join** between two relations returns those tuples from the one relation for which there exists no corresponding matches (according to join condition) in tuples of the other relation.

**left anti-join** or called **ONLY anti-join** ( $R \triangleright S$ ) retains those tuples of  $R$  which do not have a match with  $S$

$$R \triangleright S = R - (R \bowtie S)$$

**right anti-join** ( $R \triangleleft S$ ) retains those tuples of  $S$  which do not have a match with  $R$

$$R \triangleleft S = S - (R \bowtie S)$$

**anti-join** is not commutative.

# Problems on Relational Algebra

Q. Which of the following query transformations (i.e. replacing the l.h.s. expression by the r.h.s. expression) are incorrect?

$R_1$  and  $R_2$  are relations,  $C_1$  and  $C_2$  are selection conditions, and  $A_1$  and  $A_2$  are attributes of  $R_1$ .

- (a)  $\sigma_{C_1}(\sigma_{C_2}(R_1)) \rightarrow \sigma_{C_2}(\sigma_{C_1}(R_1))$
- (b)  $\sigma_{C_1}(\pi_{A_1}(R_1)) \rightarrow \pi_{A_1}(\sigma_{C_1}(R_1))$
- (c)  $\sigma_{C_1}(R_1 \cup R_2) \rightarrow \sigma_{C_1}(R_1) \cup \sigma_{C_1}(R_2)$
- (d)  $\pi_{A_2}(\sigma_{C_1}(R_1)) \rightarrow \sigma_{C_1}(\pi_{A_2}(R_1))$

[GATE1998]

# Problems on Relational Algebra

Q. Suppose  $R_1(A, B)$  and  $R_2(C, D)$  are two relation schemas. Let  $r_1$  and  $r_2$  be the corresponding relation instances.  $B$  is a foreign key that refers to  $C$  in  $R_2$ . If the data in  $r_1$  and  $r_2$  satisfy referential integrity constraints, which of the following is ALWAYS TRUE?

- (a)  $\pi_B(r_1) - \pi_C(r_2) = \phi$
- (b)  $\pi_C(r_2) - \pi_B(r_1) = \phi$
- (c)  $\pi_B(r_1) = \pi_C(r_2)$
- (d)  $\pi_B(r_1) - \pi_C(r_2) \neq \phi$

[GATE2012]

# Problems on Relational Algebra

Q. Give a relational algebra expression using only the minimum number of operators from  $\{\cup, -\}$  which is equivalent to  $R \cap S$ .  
[GATE1994]

# Problems on Relational Algebra

Q. Consider a join of a relation  $R$  with a relation  $S$ . If  $R$  has  $m$  tuples and  $S$  has  $n$  tuples, then the maximum and minimum sizes of the join respectively are:

- (a)  $m+n$  and 0
- (b)  $mn$  and 0
- (c)  $m+n$  and  $|m-n|$
- (d)  $mn$  and  $m+n$

[GATE1999]

Q. Consider the following relation  $P(X, Y, Z)$ ,  $Q(X, Y, T)$  and  $R(Y, V)$ :  
How many tuples will be returned by the following relational algebra query?

$$\pi_x(\sigma_{(P.Y=R.Y \wedge R.V=V(P \times R))}) - \pi_x(\sigma_{(Q.Y=R.Y \wedge Q.T > 2(Q \times R))})$$

(a) 3

(b) 1

(c) 2

(d) 4

[GATE2019]

Ans: Option (b)

P		
X	Y	Z
X1	Y1	Z1
X1	Y1	Z2
X2	Y2	Z2
X2	Y4	Z4

Q		
X	Y	T
X2	Y1	2
X1	Y2	5
X1	Y1	6
X3	Y3	1

R	
Y	V
Y1	V1
Y3	V2
Y2	V3
Y2	V2

# Types of Relational Calculus

- (a) Tuple Relational Calculus (TRC)
- (b) Domain Relational Calculus (DRC)

TRC and DRC are **equivalent** in power (when only safe queries are concerned), i.e., any query expressed through TRC do have a parallel query in DRC that serve the same purpose.

TRC and DRC are also equivalent in power with relational algebra.

# Tuple Relational Calculus

**Syntax:**  $\{t.attributes \mid \text{range relation of } t \text{ AND conditions}(t)\}$

$P(A,B,C)$

A	B	C
a <sub>1</sub>	b <sub>1</sub>	c <sub>1</sub>
a <sub>2</sub>	b <sub>1</sub>	c <sub>1</sub>
a <sub>3</sub>	b <sub>1</sub>	c <sub>3</sub>
a <sub>4</sub>	b <sub>1</sub>	c <sub>2</sub>
a <sub>1</sub>	b <sub>2</sub>	c <sub>1</sub>

# Tuple Relational Calculus

## Atomic expressions:

Range relation:

$R(t)$

Conditions:

$t.A \theta \text{ constant}$

$t_1.A \theta t_2.B$

## Composite expressions:

Range relation:

$R_1(t_1) \wedge R_2(t_2) \wedge \dots \wedge R_n(t_n)$

Conditions:

(i) with free variables:

$F_1 \wedge F_2, F_1 \vee F_2, \neg F_1$

(ii) with bounded variables using quantifiers:  $\forall t(F), \exists t(F)$

# Tuple Relational Calculus

List the names and addresses of all employees who work for department named 'CSE'. The database schema is as following:

EMP(ENAME, EADDRESS, EDOB, ESAL, DNO)

DEPT(DNO, DNAME, DMGR)

EMP.DNO is foreign key to DEPT.DNO

$$\{t.ENAME, t.EADDRESS \mid EMP(t) \wedge (\exists d)(DEPT(d) \wedge d.DNAME='CSE' \wedge d.DNO=t.DNO)\}$$

# Domain Relational Calculus

**Syntax:** {<attributes> | domain constraint of attributes AND conditions on attributes}

P(A,B,C)

# Domain Relational Calculus

**Formal Definition:** An expression in the domain relational calculus is of the form

$$\{ \langle x_1, x_2, \dots, x_n \rangle \mid P(x_1, x_2, \dots, x_n) \}$$

where  $x_1, x_2, \dots, x_n$  represent domain variables,  $P$  represents a formula composed of atoms, as was the case in the tuple relational calculus.

An atom in the domain relational calculus has one of the following forms:

- $\langle x_1, x_2, \dots, x_n \rangle \in r$ , where  $r$  is a relation on  $n$  attributes and  $x_1, x_2, \dots, x_n$  are domain variables or domain constants.
- $x \theta y$ , where  $x$  and  $y$  are domain variables and  $\theta$  is a comparison operator. We require that attributes  $x$  and  $y$  have domains that can be compared by  $\theta$ .
- $x \theta c$ , where  $x$  is a domain variable,  $\theta$  is a comparison operator, and  $c$  is a constant in the domain of the attribute for which  $x$  is a domain variable.

We build up formulae from atoms by using the following recursively applied rules:

- An atom is a formula.
- If  $P$  is a formula, then so are  $\neg P$  and  $(P)$ .
- If  $P_1$  and  $P_2$  are formulae, then so are  $P_1 \wedge P_2$ ,  $P_1 \vee P_2$ , and  $P_1 \Rightarrow P_2$
- If  $P(x)$  is a formula in  $x$ , where  $x$  is a domain variable, then:  $\exists x(P(x))$  and  $\forall x(P(x))$  are also formulae.
